How do we optimise programs today?

Program

Compiler

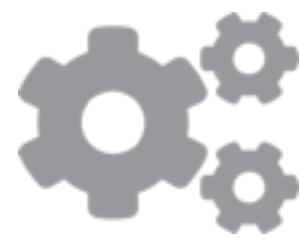

Performance ?

- Change the program manually
- Change compiler options

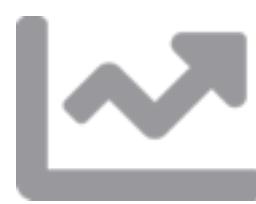

How do we optimise programs today?

Program

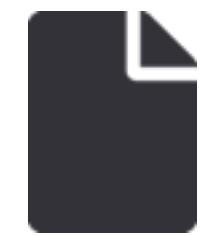

Compiler

Performance ?

```
for (i = 0; i < N; ++i) {  
    for (j = 0; j < N; ++j){  
        C[i][j] = 0;  
        for (k = 0; k < N; ++k)  
            C[i][j] += A[i][k] * B[k][j]; } }
```

How do we optimise programs today?

Program

Compiler

Performance ?

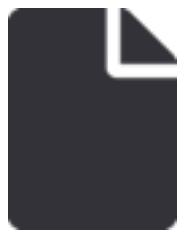

```
for (i = 0; i < N; ++i) {  
    for (j = 0; j < N; ++j){  
        C[i][j] = 0;  
        for (k = 0; k < N; ++k)  
            C[i][j] += A[i][k] * B[k][j]; } }
```

CPUs

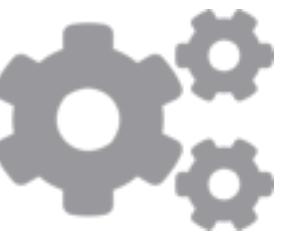

- Blocking / Tiling
- Exploit ILP
- Exploit locality

```
for (ii = 0; ii < N; ii += ib) {  
    for (kk = 0; kk < N; kk += kb) {  
        for (j=0; j < N; j += 2) {  
            for(i = ii; i < ii + ib; i += 2 ) {  
                if (kk == 0)  
                    acc00 = acc01 = acc10 = acc11 = 0;  
                else {  
                    acc00 = C[i + 0][j + 0];  
                    acc01 = C[i + 0][j + 1];  
                    acc10 = C[i + 1][j + 0];  
                    acc11 = C[i + 1][j + 1]; }  
                for (k = kk; k < kk + kb; k++) {  
                    acc00 += A[k][j + 0] * B[i + 0][k];  
                    acc01 += A[k][j + 1] * B[i + 0][k];  
                    acc10 += A[k][j + 0] * B[i + 1][k];  
                    acc11 += A[k][j + 1] * B[i + 1][k];  
                }  
                C[i + 0][j + 0] = acc00;  
                C[i + 0][j + 1] = acc01;  
                C[i + 1][j + 0] = acc10;  
                C[i + 1][j + 1] = acc11; } } } }
```

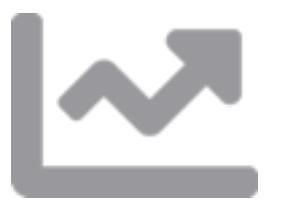

How do we optimise programs today?

Program

Compiler

Performance ?

```
for (i = 0; i < N; ++i) {  
    for (j = 0; j < N; ++j){

How do we optimise programs today?

From the LLVM manual:

Code Generation Options

`-O0, -O1, -O2, -O3, -Ofast, -Os, -Oz, -Og, -O, -O4`

Specify which optimization level to use:

`-O0` Means "no optimization": this level compiles the fastest and generates the most debuggable code.

`-O1` Somewhere between `-O0` and `-O2`.

`-O2` Moderate level of optimization which enables most optimizations.

`-O3` Like `-O2`, except that it enables optimizations that take longer to perform or that may generate larger code (in an attempt to make the program run faster).

`-Ofast` Enables all the optimizations from `-O3` along with other aggressive optimizations that may violate strict compliance with language standards.

`-Os` Like `-O2` with extra optimizations to reduce code size.

`-Oz` Like `-Os` (and thus `-O2`), but reduces code size further.

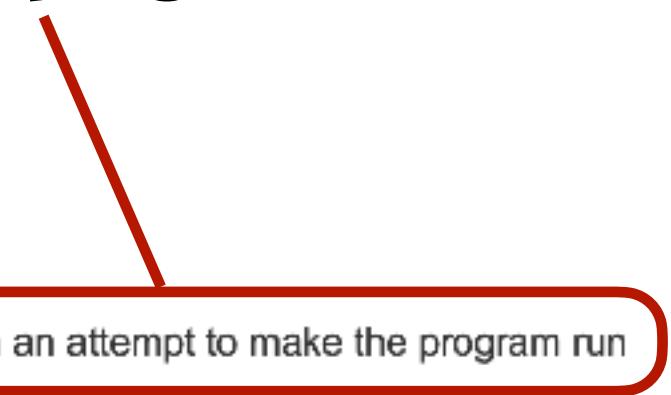

`-Og` Like `-O1`. In future versions, this option might disable different optimizations in order to improve debuggability.

`-O` Equivalent to `-O2`.

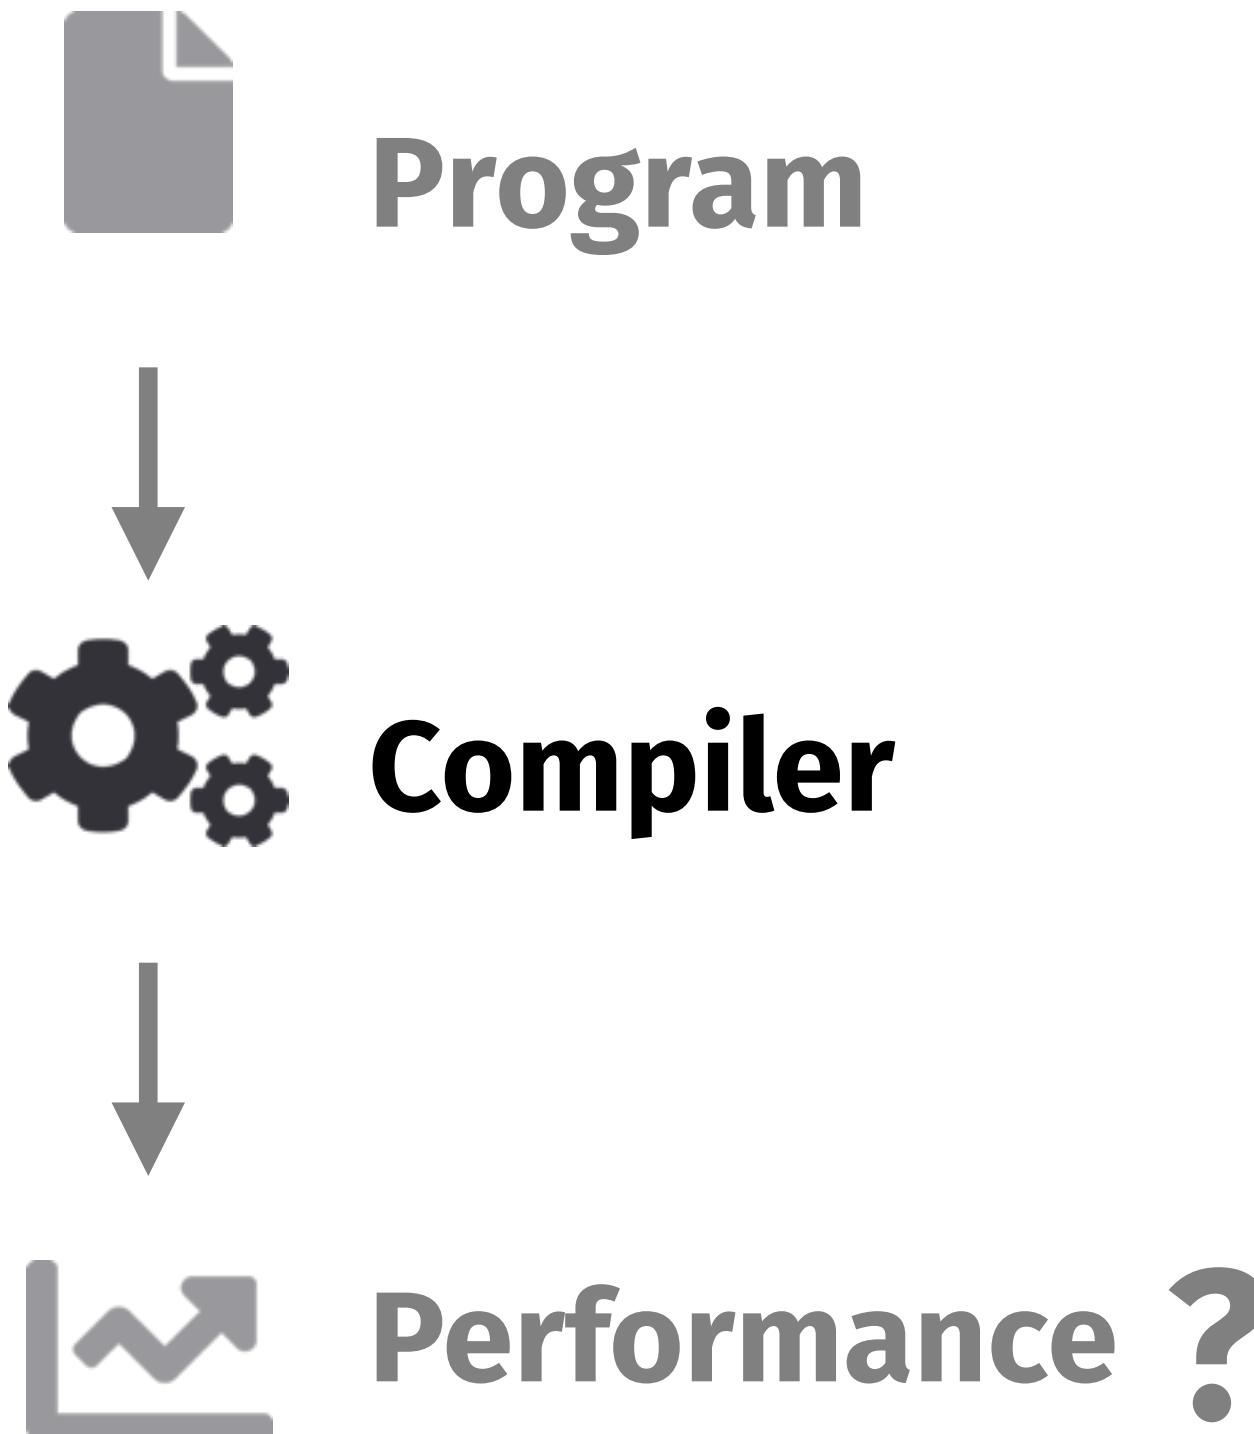

`-O4` and higher

Currently equivalent to `-O3`

"... in an attempt to make the program run faster"

How do we optimise programs today?

Code Generation Options

-O0, -O1, -O2, -O3, -Ofast, -Os, -Oz, -Og, -O, -O4

Specify which optimization level to use:

-O0 Means "no optimization": this level compiles the fastest and generates the most debuggable code.

-O1 Somewhere between **-O0** and **-O2**.

-O2 Moderate level of optimization which enables most optimizations.

-O3 Like **-O2**, except that it enables optimizations that take longer to perform or that may generate larger code (in an attempt to make the program run faster).

-Ofast Enables all the optimizations from **-O3** along with other aggressive optimizations that may violate strict compliance with language standards.

-Os Like **-O2** with extra optimizations to reduce code size.

-Oz Like **-Os** (and thus **-O2**), but reduces code size further.

-Og Like **-O1**. In future versions, this option might disable different optimizations in order to improve debuggability.

-O Equivalent to **-O2**.

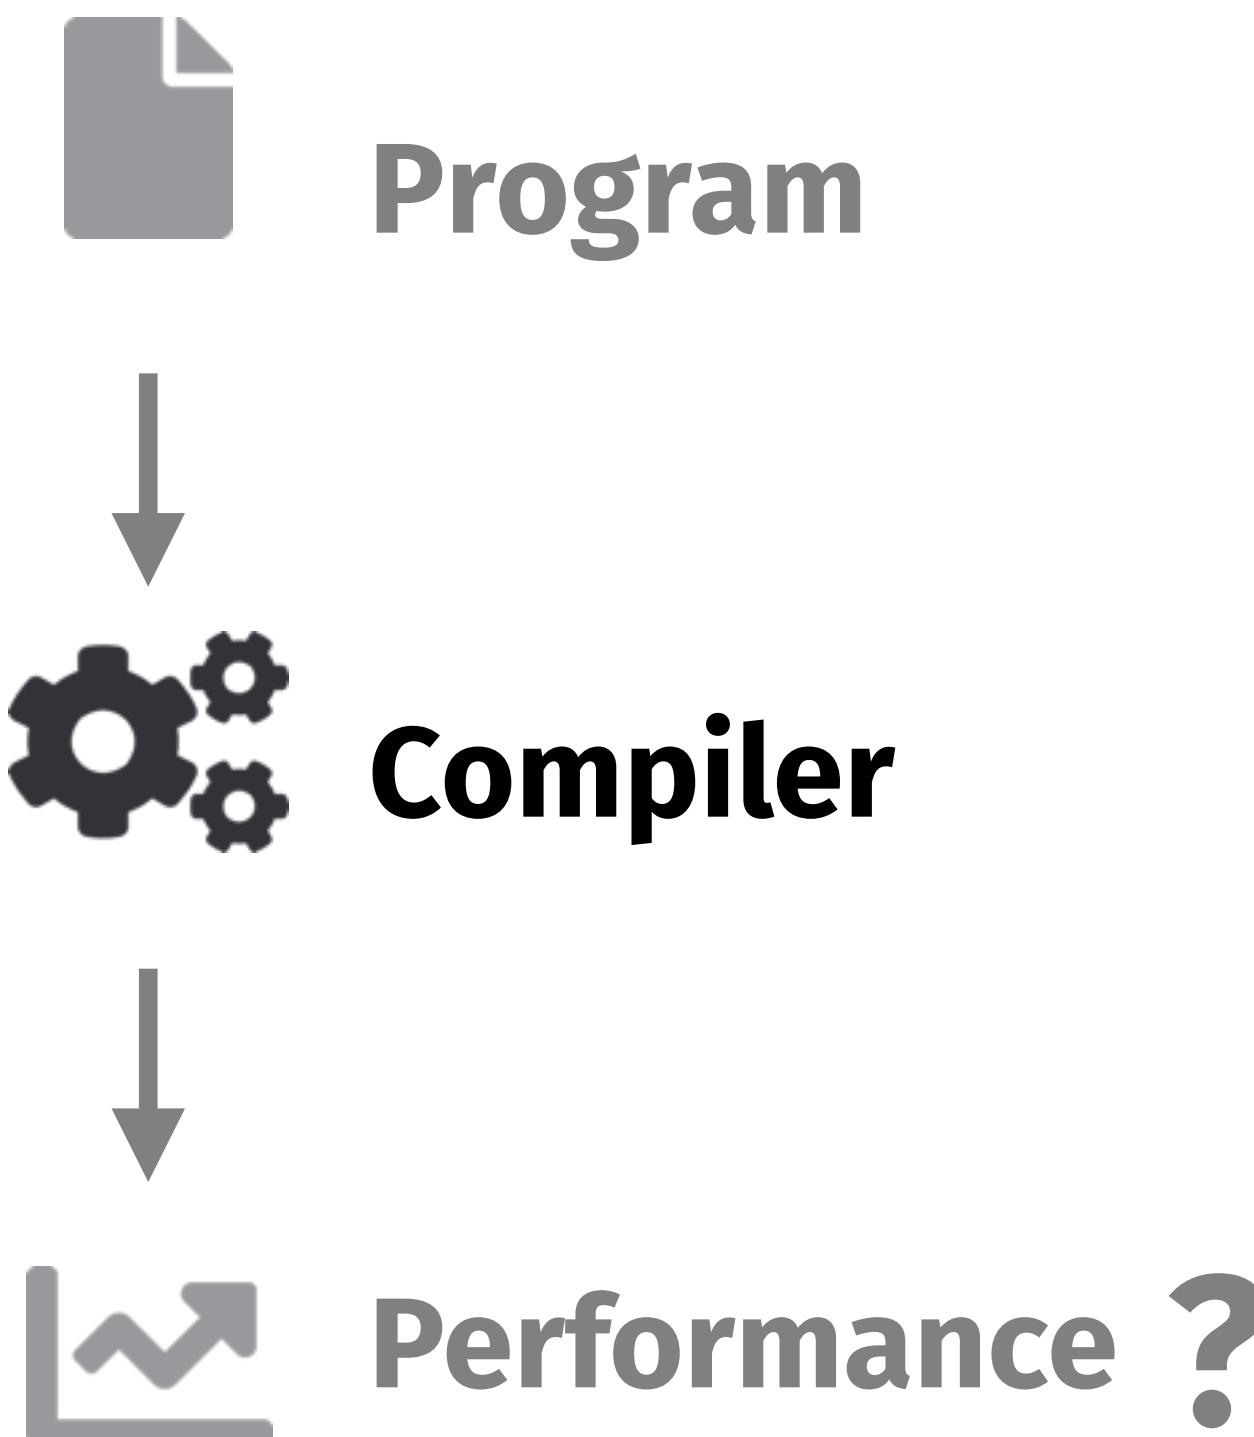

-O4 and higher

Currently equivalent to **-O3**

"... in an attempt to make the program run faster"

-O3

How do we optimise programs today?

-O Equivalent to **-O2**.

-O4 and higher

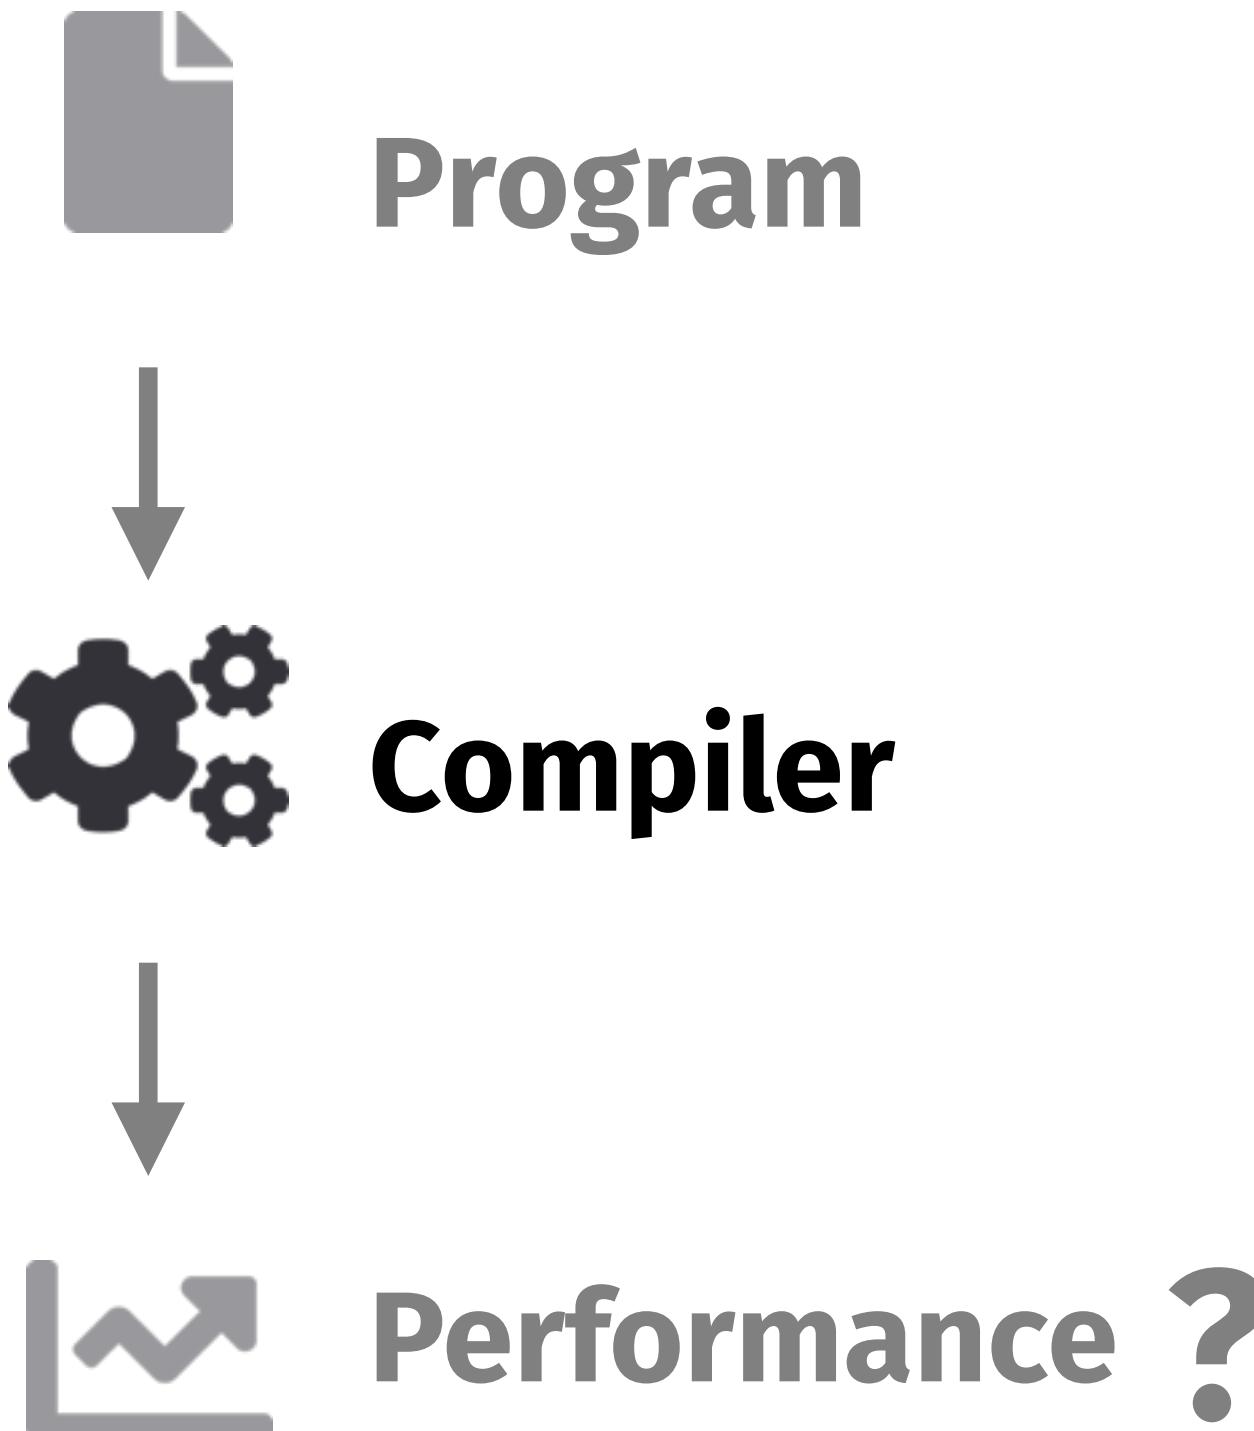

Currently equivalent to **-O3**

"... in an attempt to make the program run faster"

-O3

Intel compiler:

-opt-matmul

Options **-opt-matmul** and **/Qopt-matmul** tell the compiler to **identify matrix multiplication loop nests (if any) and replace them with a matmul library call** for improved performance. The resulting executable **may get additional performance gain on Intel® microprocessors** than on non-Intel microprocessors.

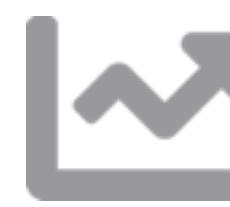

How do we optimise programs today?

Program

Impossible to understand what is going on in the compiler ⇒ Hard to control optimisations

Performance ?

From the LLVM manual:

Code Generation Options

-O0, -O1, -O2, -O3, -Ofast, -Os, -Oz, -Og, -O, -O4

Specify which optimization level to use:

-O0 Means "no optimization": this level compiles the fastest and generates the most debuggable code.

-O1 Somewhere between **-O0** and **-O2**.

-O2 Moderate level of optimization which enables most optimizations.

-O3 Like **-O2**, except that it enables optimizations that take longer to perform or that may generate larger code (in an attempt to make the program run faster).

"... in an attempt to make the program run faster"

-Os Like **-O2** with extra optimizations to reduce code size.

-Oz Like **-Os** (and thus **-O2**), but reduces code size further.

-Og Like **-O1**. In future versions, this option might disable different optimizations in order to improve debuggability.

-O Equivalent to **-O2**.

-O4 and higher

Currently equivalent to **-O3**

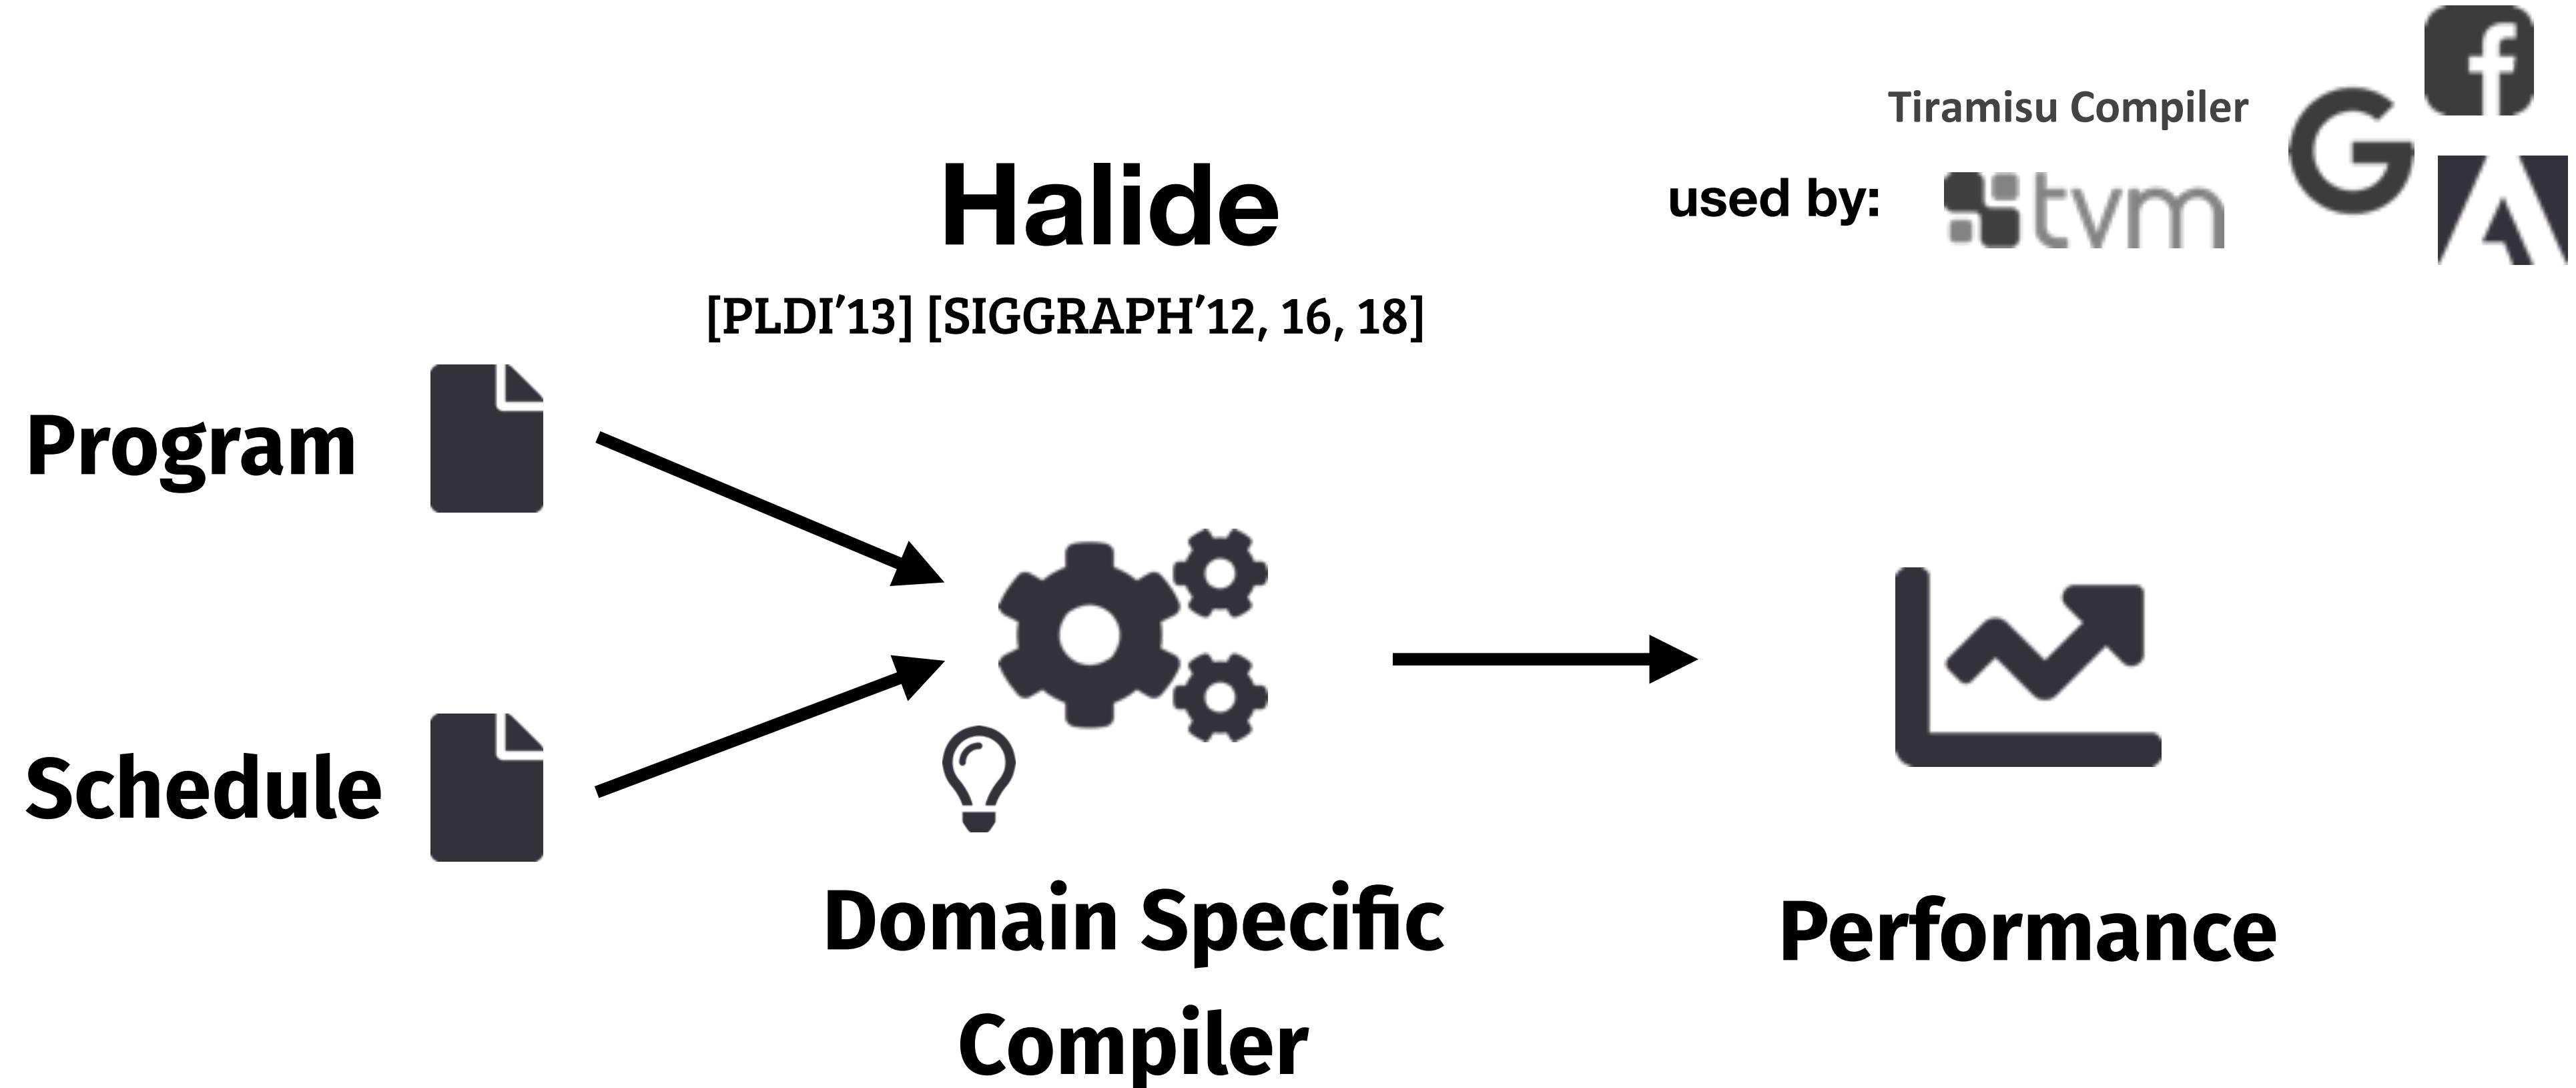

-O3

Intel compiler:

-opt-matmul

Options **-opt-matmul** and **/Qopt-matmul** tell the compiler to **identify matrix multiplication loop nests (if any) and replace them with a matmul library call** for improved performance. The resulting executable **may get additional performance gain on Intel® microprocessors** than on non-Intel microprocessors.

Separate Program from Optimisations

Separation in Program and Schedule allows for portable performance

Halide - Program vs. Schedule

Program

Domain Specific Language
embedded in C++

```
Func prod("prod");
RDom r(0, size);
prod(x, y) += A(x, r) * B(r, y);
out(x, y) = prod(x, y);
```

Schedule

C++ API for selecting
optimisation options

```
const int warp_size = 32;
const int vec_size = 2;
const int x_tile = 3;
const int y_tile = 4;
const int y_unroll = 8;
const int r_unroll = 1;

Var xi, yi, xio, xii, yii, xo, yo, x_pair, xio, ty;
RVar rxo, rxi;

out.bound(x, 0, size)
    .bound(y, 0, size)
    .tile(x, y, xi, yi, x_tile * vec_size * warp_size, y_tile * y_unroll)
    .split(yi, ty, yi, y_unroll)
    .vectorize(xi, vec_size)
    .split(xi, xio, xii, warp_size)
    .reorder(xio, yi, xii, ty, x, y)
    .unroll(xio)
    .unroll(yi)
    .gpu_blocks(x, y)
    .gpu_threads(ty)
    .gpu_lanes(xii);
prod.store_in(MemoryType::Register)
    .compute_at(out, x)
    .split(x, xo, xi, warp_size * vec_size, TailStrategy::RoundUp)
    .split(y, ty, y, y_unroll)
    .gpu_threads(ty)
    .unroll(xi, vec_size)
    .gpu_lanes(xi)
    .unroll(xo)
    .unroll(y)
    .update()
    .split(x, xo, xi, warp_size * vec_size, TailStrategy::RoundUp)
    .split(y, ty, y, y_unroll)
    .gpu_threads(ty)
    .unroll(xi, vec_size)
    .gpu_lanes(xi)
    .split(r.x, rxo, rxi, warp_size)
    .unroll(rxi, r_unroll)
    .reorder(xi, xo, y, rxi, ty, rxo)
    .unroll(xo)
    .unroll(y);

Var Bx = B.in().args()[0], By = B.in().args()[1];
Var Ax = A.in().args()[0], Ay = A.in().args()[1];
B.in()
    .compute_at(prod, ty)
    .split(Bx, xo, xi, warp_size)
    .gpu_lanes(xi)
    .unroll(xo).unroll(By);

A.in()
    .compute_at(prod, rxo)
    .vectorize(Ax, vec_size)
    .split(Ax, xo, xi, warp_size)
    .gpu_lanes(xi)
    .unroll(xo).split(Ay, yo, yi, y_tile)
    .gpu_threads(yi).unroll(yo);

A.in().in().compute_at(prod, rxi)
    .vectorize(Ax, vec_size)
    .split(Ax, xo, xi, warp_size)
    .gpu_lanes(xi)
    .unroll(xo).unroll(Ay);

set_alignment_and_bounds(A, size);
set_alignment_and_bounds(B, size);
set_alignment_and_bounds(out, size);
```

Schedule much harder to write and reason about than functional program!

Halide - Program vs. Schedule

Program

```
Func prod("prod")
RDom r(0, size);
prod(x, y)
out(x, y) =
```

```
...  
out.bound(x, 0, size)  
.bound(y, 0, size)  
.tile(x, y, xi, yi, x_tile * vec_size * warp_size, y_tile * y_unroll)  
.split(vi, ty, yi, y_unroll)  
.vectorize(xi, vec_size)  
.split(xi, xio, xii, warp_size)  
.reorder(xio, yi, xii, ty, x, y)  
.unroll(xio)  
.unroll(yi)  
.gpu_blocks(x, y)  
.gpu_threads(ty)  
.gpu_lanes(xii);  
...
```

⇒ unclear semantics ⇒ unclear how to automatically generate schedules

Schedule

```
const int warp_size = 32;  
const int vec_size = 2;  
const int x_tile = 3;  
const int y_tile = 4;  
const int y_unroll = 8;  
const int r_unroll = 1;  
  
Var xi, yi, xio, xii, yii, xo, yo, x_pair, xii, ty;  
RVar rxo, rxi;  
  
out.bound(x, 0, size)  
.bound(y, 0, size)  
.tile(x, y, xi, yi, x_tile * vec_size * warp_size, y_tile * y_unroll)  
.split(yi, ty, yi, y_unroll)  
.vectorize(xi, vec_size)
```

```
set_alignment_and_bounds(A, size);
set_alignment_and_bounds(B, size);
set_alignment_and_bounds(out, size);
```

Halide - Program vs. Schedule

Program

Unintuitive semantics: Why are these lines repeated

Schedule

Domain Specific Language

C++ API for selecting

```
prod.store_in(MemoryType::Register).compute_at(out, x)
    .split(x, xo, xi, warp_size * vec_size, TailStrategy::RoundUp)
    .split(y, ty, y, y_unroll)
    .gpu_threads(ty).unroll(xi, vec_size).gpu_lanes(xi)
    .unroll(xo).unroll(y).update()
    .split(x, xo, xi, warp_size * vec_size, TailStrategy::RoundUp)
    .split(y, ty, y, y_unroll)
    .gpu_threads(ty).unroll(xi, vec_size).gpu_lanes(xi)
    .split(r.x, rxo, rxi, warp_size)
    .unroll(rxi, r_unroll).reorder(xi, xo, y, rxi, ty, rxo).unroll(xo).unroll(y);
```

Unintuitive semantics: “Update: Get a handle on an update step for the purposes of scheduling it”

```
const int warp_size = 32;
const int vec_size = 2;
const int x_tile = 3;
const int y_tile = 4;
const int y_unroll = 8;
const int r_unroll = 1;

Var xi, yi, xio, xii, yii, xo, yo, x_pair, xio, ty;
RVar rxo, rxi;

out.bound(x, 0, size)
    .bound(y, 0, size)

set_alignment_and_bounds(A, size);
set_alignment_and_bounds(B, size);
set_alignment_and_bounds(out, size);
```

Schedules are second class citizens.

We should write schedules in a proper programming language!

ELEVATE

A programming language for program optimizations

ELEVATE is a functional language that allows to compose individual *program transformations* into larger *optimisation strategies*.

ELEVATE programs are composed of (possibly recursive) functions:

```
def transform(p: Program): RewriteResult[Program] = implementation
```

Program transformations are expressed as functions with a particular type:

```
Program → RewriteResult[Program]
```

Optimisation strategies are composed functions with the same type

A **RewriteResult** can either be **Success** or **Failure**

A successfully applied transformation contains the transformed program.

A unsuccessfully applied transformation is indicated as failure.

ELEVATE for optimising LIFT programs

ELEVATE can be used to optimise programs written in different languages

In this talk I focus on programs written in two functional languages:

- the data parallel LIFT programming language
- the **FSmooth** language used for automatic differentiation

We intend to use ELEVATE for additional high-level languages like TensorFlow

LIFT: More info at <http://www.lift-project.org> and papers at: [ICFP 2015] [CASES 2016] [CGO 2017 & 2018]

Abstract

We describe a language for defining term rewriting strategies, and its application to the production of program optimizers. Valid transformations on program terms can be described by a set of rewrite rules; rewriting strategies are used to describe when and how the various rules should be applied in order to obtain the desired optimization effects. Separating rules from strategies in this fashion makes it easier to reason about the behavior of the optimizer as a whole, compared to traditional monolithic optimizer implementations. We illustrate the expressiveness of our language by

A program optimizer transforms the source code of a program into a program that has the same meaning, but is more efficient. On the level of specification and documentation, optimizers are often presented as a set of correctness-preserving *rewrite rules* that transform code fragments into equivalent more efficient code fragments (e.g., see Table 5). This is particularly attractive for functional language compilers (e.g., [3, 4, 24]) that operate via successive small transformations, and don't rely on analyses requiring significant auxiliary data structures. The paradigm provided by conventional rewrite engines is to compute the normal form of a term with respect to a set of rewrite rules. However,

Generic ELEVATE traversals

ELEVATE **defines generic traversals if three basic traversals are defined for P**

```
// applies strategy to all direct subexpressions
def all[P]: Strategy[P] ⇒ Strategy[P]

// applies strategy to one direct subexpression
def one[P]: Strategy[P] ⇒ Strategy[P]

// applies strategy to at least one direct subexpression
def some[P]: Strategy[P] ⇒ Strategy[P]

def oncetd[P](s: Strategy[P])
  (p: P): RewriteResult[P] = (s <+ one(oncetd(s)))(p)

def tryAll[P](s: Strategy[P])
  (p: P): RewriteResult[P] = (all(tryAll(try(s))) `;` try(s))(p)

...
```

Generic ELEVATE normalisation

ELEVATE **defines a normalisation strategy based on the generic traversals**

```
def normalize[P]: Strategy[P] => Strategy[P] = s => repeat(oncetd(s))
```

This applies a given strategy until this is not applicable anymore

Complex compiler optimisations in ELEVATE

With ELEVATE we easily express traditional compiler optimisations, like tiling or loop reordering:

```
def tileNDRec: Int ⇒ Int ⇒ Strategy[Lift] = dim ⇒ n ⇒ dim match {
  case x if x ≤ 0 ⇒ id()
  case 1 ⇒ function(splitJoin(n))
  case 2 ⇒ fmap(function(splitJoin(n))) `;` function(splitJoin(n)) `;` shiftDim(2)
  case i ⇒ fmap(tileNDRec(dim-1)(n)) `;` tileNDRec(1)(n) `;` shiftDim(i)
}
```

```
def reorder: Seq[Int] ⇒ Strategy[Lift] = perm ⇒ {
  if(perm.length = 1) return id
  (perm.head match {
    case 1 ⇒ fmap(reorder(perm.tail.map(_-1)))
    case x ⇒
      val transposes = x-1
      shiftDimension(transposes) `;`
      moveTowardsArgument(transposes)(fmap(reorder(perm.tail.map(y ⇒ if(y > x) y-1 else y ))))
  }) `;` RNF `;` LCNF
}
```

Complex compiler optimisations in ELEVATE

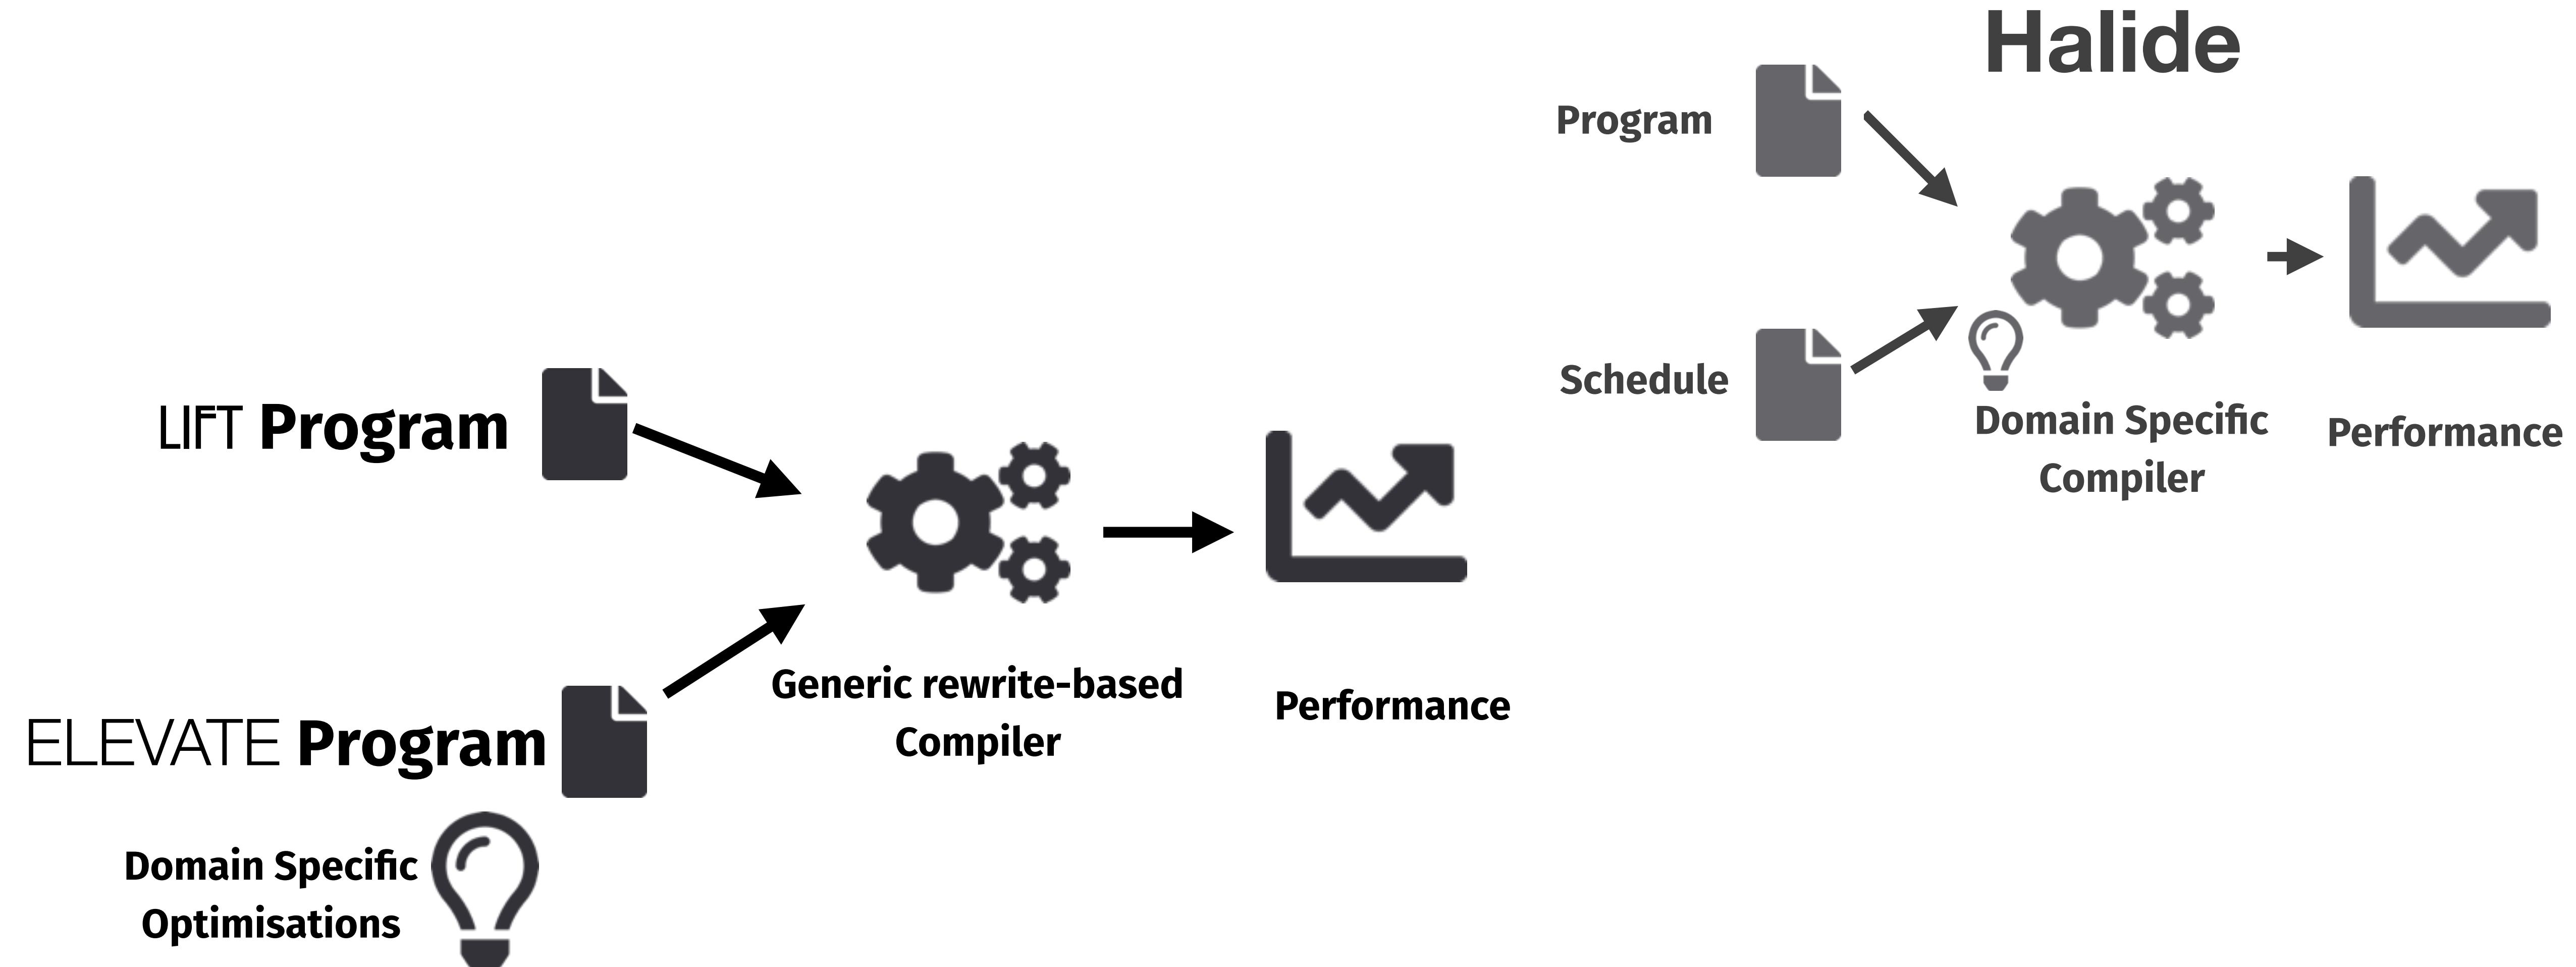

With ELEVATE we easily express traditional compiler optimisations, like tiling or loop reordering:

```
def tileNDRec: Int ⇒ Int ⇒ Strategy[Lift] = dim ⇒ n ⇒ dim match {
  case x if x ≤ 0 ⇒ id()
  case 1 ⇒ function(splitJoin(n))
  case 2 ⇒ fmap(function(splitJoin(n))) `;` function(splitJoin(n)) `;` shiftDim(2)
  case _ ⇒ fusingNDP(tiling(1) `;` shiftNDP(1) `;` shiftDim(1))
```

```
float[B][A]
1. float[bTile][B/bTile][A]           // traverse to innermost dim and apply split join
2. float[bTile][B/bTile][aTile][A/aTile] // apply splitJoin to next `map` going inner → outer
3. float[bTile][aTile][B/bTile][A/aTile] // reorder tiles using map(transpose)
```

```
if(perm.length = 1) return id
(perm.head match {
  case 1 ⇒ fmap(reorder(perm.tail.map(_-1)))
  case x ⇒
    val transposes = x-1
    shiftDimension(transposes) `;`
    moveTowardsArgument(transposes)(fmap(reorder(perm.tail.map(y ⇒ if(y > x) y-1 else y ))))
}) `;` RNF `;` LCNF
}
```

Efficient Differentiable Programming in a Functional Array-Processing Language

AMIR SHAIKHHA, University of Oxford, United Kingdom

ANDREW FITZGIBBON, Microsoft Research, United Kingdom

DIMITRIOS VYTINIOTIS, DeepMind, United Kingdom

SIMON PEYTON JONES, Microsoft Research, United Kingdom

We present a system for the automatic differentiation (AD) of a higher-order functional array-processing language. The core functional language underlying this system simultaneously supports both source-to-source forward-mode AD and global optimisations such as loop transformations. In combination, gradient computation with forward-mode AD can be as efficient as reverse mode, and that the Jacobian matrices required for numerical algorithms such as Gauss-Newton and Levenberg-Marquardt can be efficiently computed.

CCS Concepts: • Mathematics of computing → Automatic differentiation; • Software and its engineering → Functional languages; *Domain specific languages*.

Additional Key Words and Phrases: Linear Algebra, Differentiable Programming, Optimising Compilers, Loop Fusion, Code Motion.

ACM Reference Format:

... in the summer of 1958 John McCarthy decided to investigate differentiation as an interesting symbolic computation problem, which was difficult to express in the primitive

5 EFFICIENT DIFFERENTIATION

...

One of the key challenges for applying these rewrite rules is the order in which these rules should be applied.

We apply these rules based on **heuristics** and **cost models for the size of the code** (which is used by many optimising compilers, especially the ones for just-in-time scenarios). Furthermore, based on heuristics, we ensure that certain rules are applied only when some specific other rules are applicable. For example, the loop fission rule (Figure 8g) is usually applicable only when it can be combined with tuple projection partial evaluation rules (Figure 8f). **We leave the use of search strategies for automated rewriting** (e.g., using Monte-Carlo tree search [De Mesmay et al. 2009]) **as future work**.

$\text{ifold } (\text{fun } a i \rightarrow \text{if}(i = e_0) \text{ then } e_1 \text{ else } a) z n \rightsquigarrow \text{let } a = z \text{ in } \text{let } i = e_0 \text{ in } e_1 \text{ (if } e_0 \text{ does not mention } a \text{ or } i\text{)}$

(e) Loop Normalisation Rules

$\text{fst } (e_0, e_1) \rightsquigarrow e_0$	$\text{ifold } (\text{fun } a i \rightarrow (f_0(\text{fst } a)i, f_1(\text{snd } a)i) \rightsquigarrow (\text{ifold } f_0 z_0 n, \text{ifold } f_1 z_1 n)) (z_0, z_1) n$
---	---

(g) Loop Fission Rule

(f) Tuple Normalisation Rules

```

def funToLet(e: FSmooth): RewriteResult[FSmooth] = e match {
  case Application(Abstraction(Seq(x), e0, _, Seq(e1), _)) =>
    Success(Let(x, e1, e0))
  case _ => Failure(funToLet)
}

def additionZero(e: FSmooth): RewriteResult[FSmooth] = e match {
  case Application(`+`(_), Seq(e, ScalarValue(0)), _) =>
    Success(e)
  case Application(`+`(_), Seq(ScalarValue(0), e), _) =>
    Success(e)
  case _ => Failure(additionZero)
}

def trivialFold(e: FSmooth): RewriteResult[FSmooth] = e match {
  case Application(`ifold`(_), Seq(f, z, ScalarValue(0)), _) =>
    Success(z)
  case _ => Failure(trivialFold)
}

...

```

Fig. 8. Transformation Rules for \tilde{F} . Even though none of these rules are AD-specific, the rules of Figure 8f and Figure 8g are more useful in the AD context.

ELEVATE for optimising FSmooth programs

Example 5. It is known that for a matrix M , the following equality holds $(M^T)^T = M$. We show how we can derive the same equality in dF. In other words, we show that:

```
matrixTranspose (matrixTranspose M) = M
```

```
let MT =
  build(length M[0]) (fun i ->
    build(length M) (fun j ->
      M[j][i] )) in
build(length MT[0]) (fun i ->
  build(length MT) (fun j ->
    MT[j][i] ))
```

Now, by applying the loop fusion rules (cf. Figure 8c) and performing further partial evaluation, the following expression is derived:

```
build(length M) (fun i ->
  build(length M[0]) (fun j ->
    M[i][j] ))
```

```
normalize()
buildGet <+
lengthBuild <+
letPartialEvaluation <+
conditionalPartialEvaluation <+
conditionApplication <+
letApplication <+
funToLet <+
letFission <+
letInitDuplication
).apply(
  fun(M => matrixTranspose(matrixTranspose(M)))
)
```

Left choice combinator

ELEVATE

A programming language for program optimizations

This is work in progress.

No evaluation yet, and some open questions and challenges:

- How do we evaluate ELEVATE?
- How do we design a programming interface friendly to systems programmers?
- Can we use ELEVATE to help model stochastic searches in a design space?
- Can we automatically find good ELEVATE programs,
e.g. using machine learning or program synthesis techniques?
